

Internet Appendix to “The New Game in Town: Competitive Effects of IPOs”*

In this appendix, we present additional figures and the robustness tests not included in the main text.

Figure IA.I. Distribution of IPO events over time. The sample from which events are selected includes all nonfinancial firms in the SDC New Issues Database that went public between 1980 and 2001, a sample comprising 4,188 issuing firms. We identify the sample IPOs as those IPOs for which there is no IPO in the same industry in the six surrounding years that has a larger issuing volume. These selection criteria generate 134 IPO events.

Table IA.II**Abnormal Returns of the Industry Competitors for IPOs Whose Market Capitalization Is in the Top 10% in the Industry**

In this table we report the CAR of the industry competitors around the completion dates of IPOs. In Panel A, the IPO events are selected if their end-of-IPO month market capitalization is in the top 10% of all Compustat firms in the industry. In Panel B, the IPO events are selected in their market end-of-IPO-month capitalization is in the top 10% of all IPOs in the industry. Panel A then reports the CAR of 43,406 industry competitors (representing 150 IPO events) around completed IPO dates, both for individual firms and for the portfolio of IPO events. Panel B reports the CAR of 81,341 industry competitors (representing 433 IPO events) around completed IPO dates, both for individual firms and for the portfolio of IPO events. Abnormal returns are computed as the difference between the actual stock price return and the expected market model return over each indicated window. The market model is estimated using 255 days of daily returns ending 42 days prior to the IPO event. We report both the Patell Z-statistic and the corresponding *p*-value.

Table IA.III
Abnormal Returns for the Incumbent Firms around IPO Events using Eight-year Rolling Windows

In this table we report the CAR of the sample of 7,463 incumbent firms (representing 110 IPO events) around completed IPO dates, both for individual firms and for the portfolio of IPO events. Panel A has 7,463 incumbent firms; Panel B has 110 portfolios of incumbent firms based on the IPO events. Abnormal returns are computed as the difference between the actual stock price return and the expected market model return over each indicated window. The market model is estimated using 255 days of daily returns ending 42 days prior to the IPO event. We report significance levels using the Patell Z-statistic. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.

Table IA.IV
Abnormal Returns for the Incumbent Firms around IPO Events using Four-year Rolling Windows

In this table we report the CAR of the sample of 9,606 incumbent firms (representing 161 IPO events) around completed IPO dates, both for individual firms and for the portfolio of IPO events. Panel A has 9,606 incumbent firms; Panel B has 161 IPO portfolios of incumbent firms based on the IPO events. Abnormal returns are computed as the difference between the actual stock price return and the expected market model return over each indicated window. The market model is estimated using 255 days of daily returns ending 42 days prior to the IPO event. We report significance levels using the Patell Z-statistic. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.

Table IA.V
Abnormal Returns for the Incumbent Firms around IPO Events Excluding Low-tech and Heavy Industries

In this table we report the CAR of the sample of 8,424 incumbent firms (representing 122 IPO events) around completed IPO dates, both for individual firms and for the portfolio of IPO events. Panel A has 8,424 incumbent firms; Panel B has 122 portfolios of incumbent firms based on the IPO events, after excluding those IPO events with two-digit SIC industries 10, 12, 13, 14, 15, 16, and 17. Abnormal returns are computed as the difference between the actual stock price return and the expected market model return over each indicated window. The market model is estimated using 255 days of daily returns ending 42 days prior to the IPO event. We report significance levels using the Patell Z-statistic. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.

(-5,5)	-1.83%	-11.08	<0.001	-0.70%	-3.27	0.001

Table IA.VI
Abnormal Returns for the Incumbent Firms around IPO Events Using Six-year Rolling Windows with Ritter's IPO Universe

In this table we report the CAR of the sample of 12,151 incumbent firms (representing 137 IPO events selected from the sample 5,747 IPOs on Jay Ritter's website) around completed IPO dates, both for individual firms and for the portfolio of IPO events. The IPO events are selected if there are no larger IPOs in the same two-digit SIC industry in the surrounding six years. Panel A has 12,151 incumbent firms; Panel B has 137 portfolios of incumbent firms based on the IPO events. Abnormal returns are computed as the difference between the actual stock price return and the expected market model return over each indicated window. The market model is estimated using 255 days of daily returns ending 42 days prior to the IPO event. We report significance levels using the Patell Z-statistic. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.

Days	Panel A. Individual Firms			Panel B. Portfolio Based on IPO Events		
	Mean CAR	<i>Patell Z</i>	P-Value	Mean CAR	<i>Patell Z</i>	P-Value
(-10,1)	-1.11%	-6.11	<0.001	-1.07%	-4.08	<0.001

Table IA.VII
Abnormal Returns for the Incumbent Firms around IPO Events Using Six-year Rolling
IPOs: Fama-French 48 Industries

In this table we report the CAR of the sample of 12,476 incumbent firms (representing 119 IPO events) around completed IPO dates, both for individual firms and for the portfolio of IPO events. We define industries according to the 48-industry classifications by Fama and French. Panel A has 12,476 incumbent firms; Panel B has 119 portfolios of incumbent firms based on the IPO events. Abnormal returns are computed as the difference between the actual stock price return and the expected market model return over each indicated window. The market model is estimated using 255 days of daily returns ending 42 days prior to the IPO event. We report significance levels using the Patell Z-statistic. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.

Table IA.VIII
Abnormal Returns for the Incumbent Firms around the IPO Events Using Six-year Rolling
IPOs: Information Technology Industries

In this table we report the CAR of the sample of 2,925 incumbent firms (representing 30 IPO events) in the information technology industries around completed IPO dates, both for individual firms and for the portfolio of IPO events. Information technology industries are defined as the two-digit SIC codes under each of the following Fama-French 48 industries: Industry 22 (Electrical Equipment), 32 (Telecommunication), 34 (Business Services), 35 (Computers), 36 (Software), and 37 (Electronic Equipment). Panel A has 2,925 incumbent firms; Panel B has 30 portfolios of incumbent firms based on the IPO events. Abnormal returns are computed as the difference between the actual stock price return and the expected market model return over each indicated window. The market model is estimated using 255 days of daily returns ending 42 days prior to the IPO event. We report significance levels using the Patell Z-statistic. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.

Table IA.IX
The Effect of IPO Events on Incumbent Firms Using Age Since Founding

In this table we report estimates from a panel regression of incumbent firms' sales growth, growth in capital expenditure, growth in operating income, and abnormal stock return on an IPO indicator and control variables from 1977 to 2005. *Sales Growth* is the difference between current log sales and log sales in the previous year. *Capital Expenditure Growth* is the difference between the log of current-year capital expenditure and the log of capital expenditure in the previous year. *Operating Income Growth* is the difference between the log of current-year operating income and the log of operating income in the previous year. *Abnormal Stock Return* is the difference between daily stock returns and the value-weighted market portfolio return, compounded to an annual frequency based on fiscal years. *IPO Dummy* is an indicator variable equal to one in the IPO event year and the three following years. *Log(Age Since Listing)* is the log of the number of years between the incumbent firm's listing year and the observation year. *Log(Years from Founding to Listing)* is the log of the number of years between the incumbent firm's founding year and the listing year. *Log(Assets)* is the log of firm assets in the previous year. *Annual Underpricing* is the average level of IPO underpricing in a given year as reported in Ritter (2007). *Industry M/B Ratio* is the median industry market-to-book ratio in the previous year. Standard errors are adjusted for clustering by IPO event. *t*-statistics are reported in parentheses. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.

Table IA.X

The Effect of Leverage, Certification, and Industry Structure on Post-IPO Event Performance

In this table we report estimates from regressions of incumbent performance on its determinants and control variables. Industry-adjusted Sales Growth, Operating Income Growth, and Capital expenditure Growth are the log changes of four-year average industry-adjusted sales, operating income, and capital expenditure before IPO events to after IPO events. *Lagged Dependent Variable* is the four-year pre-IPO value of the respective dependent variable. *Leverage Ratio* is the ratio of long-term debt to market-adjusted value of assets (book value of debt plus market capitalization). *Bondrankyes* is an indicator variable equal to one if the firm has a Standard & Poor's long-term domestic issuer credit rating in the Compustat Database. *VC Backing* is an indicator variable equal to one if the firm is venture-backed. *High UW Ranking* is an indicator variable equal to one if the firm's Carter and Manaster (1990) underwriter ranking is at least nine. *Hightech* is an indicator variable equal to one if the firm is in the high-tech industry classification. *High Research Intensity* is an indicator variable equal to one if the ratio of research and development expenses to assets is in the top quartile of the sample. *High HH* is an indicator variable equal to one if the firm's Herfindahl index of industry concentration is greater than 1,800. *Log(Age)* is the log of the number of years between the incumbent firm's IPO year and the observation year. *Log(Assets)* is the log of firm assets in the previous year. *Industry Underpricing* is the median issue-day underpricing of IPOs in the industry over the year prior to the IPO event. *Industry M/B Ratio* is the median industry market-to-book ratio over the year prior to the IPO event. Standard errors are adjusted for clustering by IPO event. *t*-statistics are reported in parentheses. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.

Table IA.XI

The Effect of Leverage, Certification, and Industry Structure on Firm Survival After the IPO Events

In this table we report estimates from a probit regression of firm survival on determinants of incumbent competitiveness and control variables. The dependent variable is equal to zero if the firm was delisted within three years after the IPO with CRSP delisting codes equal to and above 500, and one otherwise. *Leverage Ratio* is the ratio of long-term debt to market-adjusted value of assets (book value of debt plus market capitalization). *Bondrankyes* is an indicator variable equal to one if the firm has a Standard & Poor's long-term domestic issuer credit rating in the Compustat database. *Good Bondrank* is an indicator variable equal to one if the firm has a Standard & Poor's long-term domestic issuer credit rating of BBB or above. *VC Backing* is an indicator variable equal to one if the firm is venture backed. *High UW Ranking* is an indicator variable equal to one if the firm's Carter and Manaster (1990) underwriter ranking is at least nine. *Hightech* is an indicator variable equal to one if the firm is in the Loughran and Ritter (2004) high-tech industry classification. *High Research Intensity* is an indicator variable equal to one if the ratio of research and development expenses to assets is in the top quartile of the sample. *High HH* is an indicator variable equal to one if the firm's Herfindahl index of industry concentration is greater than 1,800. *Return on Assets* is the ratio of operating income to assets. *Log(Age)* is the log of the number of years between the incumbent firm's IPO year and the observation year. *Log(Assets)* is the log of firm assets in the previous year. *Industry Underpricing* is the median issue-day underpricing of IPOs in the industry over the year prior to the IPO event. *Industry M/B Ratio* is the median industry market-to-book ratio over the year prior to the IPO event. Standard errors are adjusted for clustering by IPO event. Z-values are reported in parentheses. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.
